increased RFRP-3 neuronal activity in DMH nuclei and vice versa.

This work opens up a new avenue of research to support the role of circadian system to comprehend gonadal development during the maturation of reproductive axis in mice, suggesting the possibility of a common mechanism in the reproductive regulation of both seasonal and continuous breeders. This communication also indicates that temporal phase relation between the circadian serotoninergic and dopaminergic oscillations may modulate gonadal development during the process of sexual maturity in the laboratory mice. Further, there would be many inhibitory neuroendocrine mechanisms involved in the prepubertal and drug-induced (8 h relation) reproductive suppression, and RFRP-3 appears to be one of these factors. Additional studies involving administration of RFRP-3 in adult or 12 h mice and its antagonist in prepubertal or 8 h mice may strengthen the evidence supporting this suggestion.

Global influence of Cancer Statistics articles

The contribution or impact of a research article can be assessed based on the number of times the article is cited by other research articles. Each year, CA—A Cancer Journal for Clinicians publishes a series of articles called Cancer Statistics, which receives an extremely high number of citations. Over the years, Cancer Statistics articles have provided important information for cancer researchers and clinicians throughout the world. Here we report the global influence of Cancer Statistics articles and demonstrate the shift in their influence toward East Asia, where researchers have significantly increased their frequency in citing Cancer Statistics articles while showing a decreasing trend in citations by American researchers. Data for this correspondence were retrieved from the SCI-EXPANDED database of the Web of Science (WoS) of Thomson Reuters.

Figure 1 shows the annual number of citations of Cancer Statistics articles published from 2001 to 2011. During this time, these articles in general showed a citation peak in the second year of publication, as well as a higher citation peak with each successive year, indicating an increasing trend in their influence and readership. Table 1 shows the global influence of Cancer Statistics articles. As of the end of 2012, ‘Cancer Statistics, 2001’ by Greenlee et al. has been cited in 2237 research papers by 10,401 authors from 2109 institutions in 56 countries, and was published in 685 journals belonging to 99 WoS categories in science. ‘Cancer Statistics, 2008’ by Jemal et al. has the highest number of citations as of TC2012 (total number of times cited since the paper was published to 2012). It has been cited in 5544 research papers by 25,811 authors from 4530 institutions in 83 countries. In the last decade, Cancer Statistics articles have significantly increased their global influence. The most recent articles of 2009, 2010, and 2011 did not have as many citations as ‘Cancer Statistics, 2008’ (ref. 2), since the recent articles had a shorter life and time to accumulate citations. However, length of time may not be the only factor. Further analysis revealed that a reduction in the US papers citing Cancer Statistics articles has contributed to their lower citations after 2008.

Table 2 compares the number of citations, as well as the percentage of total citations that Cancer Statistics articles received from the top 10 leading countries. Since Cancer Statistics articles showed a citation peak in the second year of publication, we limit the time-frame to the first two years of article life. Citations at the end of their year can be used as a proxy of their visibility in cancer research. Furthermore, it does not vary with time, unlike the total number of citations, which can be affected by the article life, and thus can be used to provide a fair comparison among articles. Cancer Statistics articles published after 2011 were not included, as they may not have reached their citation peak.

TP, Total number of papers citing the Cancer Statistics article in its publication year and in the following year.

The G7 countries (USA, Germany, Italy, Canada, Japan, the UK and France) were ranked among the top eight (Table 2). USA was the leading source of citations for Cancer Statistics articles, contributing as much as 90% of citations in 2002, but decreased to as low as 66% and 67% in 2009 and 2010 respectively, and then dropped to 30% in 2011. Despite showing a trend of decreasing percentage before 2008, the number of US papers citing Cancer Statistics was still increasing, from 581 papers in 2001 to 1607 papers in 2008. Unexpectedly, after 2008, the number showed a sharp decrease, dropping to 1073 papers in 2010, and 492 papers in 2011. On the contrary, China, has become a major source of citations for Cancer Statistics, in both number and percentage, over the same period of time. It overtook the US in 2011, publishing 31% of all papers citing Cancer Statistics. Japan and Korea also showed significant increase in the last decade. Cancer Statistics articles appeared to have played a more significant role in the G7 countries.
role in cancer research in East Asia after 2008. The increase was also observed for Italy, Germany and the UK, although not as significant as in Asian countries.

To sum up, Cancer Statistics articles had increased their global influence in cancer research in the last decade. However, their influence on cancer research in the US might be decreasing, as indicated by the much lower percentage and frequency of citations received from the US researchers. One possible reason could be that the content of Cancer Statistics articles were not in accordance with the cancer research agenda in the US, and thus these articles are not cited as often by the US researchers. Another reason could be the decrease in funding for cancer research after 2008. It was possible that the financial crisis of 2008 might have a negative influence in scholarship and funding that supported cancer research in the US. Based on the available data, it was not clear why such a significant drop in the US citations had occurred. Nevertheless, this result did indicate a sign of warning concerning cancer research in the US. Further research is needed to see if such a trend continues.

Adaptive modifications in lip and barbel of an endangered catfish
Amblyceps arunchalensis Nath & Dey, 1989

The mountain streams of the Eastern Himalayas are perennial shallow water bodies, characterized by low temperature, highly turbulent current and sandy, rocky substratum1. Fishes are unique among vertebrates in that external sense buds especially abundant on their barbels2. Amblyceps arunchalensis Nath and Dey, 1989 has limited distribution in the torrential water bodies of North East India (Figure 1 b). The fish falls in the endangered category3. So far only taxonomic data are available and key characters include unequal jaws, reduced rectal fold, tuberculated skin and a number of adaptive modifications suitable for torrential habitat. Taste buds and mucus pores are invariably present in lips and barbels, which serve as chemo and mechanoreceptors. In the present study we describe the characteristic differences observed in the structure of lips and barbels of A. arunchalensis.

Live specimens of A. arunchalensis were collected from Ranganadi river (Figure 1 a), a northern tributary of the Brahmaputra in Lakhimpur district, Assam, India. Fishes (N = 5) were in the range of total length (TL) = 8.28–10.69 cm and body weight (BW) = 4.43–8.55 g. For SEM analysis, barbels and lips of A. arunchalensis were removed with the help of a surgical blade and fixed in 3% glutaraldehyde solution for 24 h and the prescribed methodology of SEM4 was followed. Sputtering was done with gold palladium mixture for 6 min using Emitech-SC7620 sputter coater and was viewed in FESEM (SIGMA, Zeiss, Germany) at 5 kV. Sizes of the central pores of the taste buds were measured with IMAGE J software.

In catfishes, the sense of taste is principally used to guide them to food, thereby acting as a long-range receptor5. Similar studies in case of Corydoras arcuatus and Tinca tinca have shown that numerous taste buds are present which in turn have several microvilli6,7. Presence of microvilli help them in adhering to the substratum and also act as mechano-cum-sensory receptors. The presence of these spine-like microvilli increases the
