MYCOBACTERIUM PHLEI: A NOVEL IMMUNOGENIC STRAIN AGAINST M. TUBERCULOSIS INFECTION IN EXPERIMENTAL ANIMALS

N. B. SINGH, KANCHAN SRIVASTAVA and M. S. CHOUDHURY
Division of Microbiology, Central Drug Research Institute, Lucknow 226 001, India.

The view that BCG affords protection against tuberculosis has received a set-back following the results of a controlled trial conducted in South India. Even in the past the role of BCG had been a subject of controversy. Therefore, renewed interest continues in searching for other immunogenic strains which have considerably increased during recent years. Some potential strains having immunogenic property have been identified. We describe here a strain of a typical non-pathogenic mycobacterium M. phlei (TMC 1523) which has generated Listeria type response and has also afforded protection against M. tuberculosis H$_37$Rv in mice and guinea pigs.

Mycobacteria produce two types of response when they are exposed to a homologous challenge after sensitization. The 10th to 11th day response (swelling of foot-pad after challenge) is Listeria type and the 28th day response is said to be of Koch type. Mycobacteria producing Listeria type response have shown correlation with antigenicity in mycobacteria.

The strains of mycobacteria for this study were obtained from Trudeau Mycobacterial Culture Collection Centre (TMC), Trudeau Institute Inc, Saranac Lake, New York. The cultures were maintained on Löwenstein Jensen Medium by six monthly passage. The mycobacteria were initially tested in albino Swiss mice for Listeria or Koch type response following Rook's technique and the strain, which produced Listeria type response, was selected for further studies. Out of several strains of mycobacteria tested M. phlei (TMC 1523) produced the best Listeria type response. The strain was tested in mice for its immunogenic potency against the live challenge of M. tuberculosis H$_37$Rv (TMC 201). The animals (15 in number) were vaccinated with 1 mg wet weight (approx. 2.4 x 10$^8$ colony-forming unit, cfu) of M. phlei at 4 different sites on the back subcutaneously and challenged with 1.9 x 10$^8$ cfu (1 mg wet weight/mouse) of M. tuberculosis H$_37$Rv intravenously 21 days after vaccination.

Several parameters like weekly body weight, general appearance, necropsy score, presence of acid fast bacilli in impression smears from visceral organs and survival time of animals were studied to evaluate the immunogenic potency of this strain. The degree of protection was mainly assessed on the basis of survival of the animals after challenge for 30, 60 and 90 days (S-30, S-60, S-90).

The statistical analysis of the survival data in mice suggests that sufficient degree of protection has been provided by M. phlei against virulent challenge with M. tuberculosis in mice (table 1). Other parameters also concorded with the protective effect. The control animals deteriorated in general appearance and lost body weight sooner than the experimental group after challenge. The visceral organs smear showed less number of bacilli in the vaccinated than in the control group.

M. phlei was further tested in guinea pigs which is known to be more susceptible to human tubercle bacillus infection. These guinea pigs (10 animals/group) were vaccinated with live culture of M. phlei, s/c (1 mg wet weight/animal) and challenged intracardially to obtain the survival data. The data

Figure 1. Protective values of *M. phlei* on vaccination against *M. tuberculosis* H₃⁷ Rv challenge in mice and G. pigs.

---

The presented in table 2 shows the percentage of survivors in the vaccinated group on days 30, 60 and 90 to be significantly higher. Percentage survivors in both the animal species are graphically represented in figure 1. It is obvious that the test strain affords sufficient degree of protection against human tuberculosis bacillus both in mice as well as in Guinea pigs.

The authors are grateful to Dr M. M. Dhar, for his keen interest in the work. The assistance of Sri Triloki Nath and Hori Lal is duly acknowledged.
