EFFECT OF FEEDING TRIGONELLA FOENUM GRAECUM (METHI) LEAVES ON SERUM CHOLESTEROL, TRIGLYCERIDES AND HIGH DENSITY LIPOPROTEIN CHOLESTEROL IN THE NORMAL RABBITS

VINITA CHATURVEDI and M. C. PANT
Department of Biochemistry, S. N. Medical College,

The seeds and leaves of *Trigonella foenum graecum* (Methi) are reported to have carminative, anthelmintic, antipyretic, suppurative, diuretic, aphrodisiac and emmenagogue properties useful for treatment of dropsy, chronic cough, enlargement of spleen, liver and heart diseases. The seeds of fenugreek are reported to have hypcholesterolemic activity.

The aim of the present study is to find out the effect of oral administration of the green leaves of methi on serum lipids in normal albino rabbits, whose correlation with cardiovascular system is well established.

Fresh green leaves of 'methi' bought daily from the local market, were washed and cooked in steam. Sixteen normal adult male albino rabbits were maintained on Hindustan Gold Mohr rabbit feed for a month. After this period, serum lipids were estimated twice to check constancy of their levels, which was followed by feeding of experimental diet containing 10 g cooked green leaves along with basal diet *ad libitum* for eight weeks to the experimental group animals, consisting of eight rabbits, whereas the other group of remaining eight rabbits was kept on only control diet throughout. The animals had free access to food and water, however, their daily food consumption was between 95 and 100 g. Fasting blood samples were drawn at the end of first week, second week, fourth week and eighth week.

+ Sample size in each case was 8. Figures in parentheses indicate per cent change. *P < 0.001; **P < 0.01; ***P < 0.05.
while feeding experimental diet and analysed for serum cholesterol\textsuperscript{8}, triglyceride\textsuperscript{9} and high density lipoprotein cholesterol\textsuperscript{10}. Body weight was recorded in the beginning and at the end of 1st, 2nd, 4th and 8th weeks.

The data were statistically evaluated by applying students $t$ test.

Analysis of blood samples after feeding leaves of *Trigonella foenum graecum* 10 g daily to the normal albino rabbits at the end of 1st, 2nd, 4th and 8th week revealed that there occurred a continuous lowering in serum cholesterol and triglyceride. On the other hand, HDL-cholesterol showed a continuously rising pattern. Body weight showed an increasing pattern during experiments. Upon statistical evaluation of the data, the observed changes have been found to be highly significant ($P < 0.001$ to $<0.001 \text{)}$ (table 1).

*Trigonella foenum graecum* leaves form part of spices and are consumed as a vegetable in the Indian diets. Though there are reports regarding the hypcholesterolemic effect of its seeds, no studies have yet been made on the biochemical effects caused by administration of the leaves in the body as both seeds and leaves possess almost the same composition\textsuperscript{11}.

The present study shows that the daily addition of cooked leaves to the diets of normal rabbits within eight weeks can produce significant lowering of cholesterol and triglycerides in circulation. The high density lipoprotein cholesterol is significantly increased. Obviously, the low density lipoprotein cholesterol must decline since total cholesterol shows an overall decrease. Fall in circulatory cholesterol and triglycerides brought about by the administration of fenugreek leaves is probably due to both fibre and saponin\textsuperscript{2,5,12,13}.

Biochemically, lowering of the total cholesterol, triglycerides, low density lipoprotein cholesterol and rise in high density lipoprotein cholesterol on *Trigonella foenum graecum* containing diet could provide a valuable tool for maintaining cardiovascular system in healthy conditions\textsuperscript{6,7,14}.

**LEVELS OF ARGINASE AND TRANSAMINASES IN POLYCHLORINATED DIBENZOFURAN (PCDFs) FED RATS**

P. S. DEVAMANO哈尔AN, R. SANKAR and C. S. SHYAMALA DEVI

Department of Biochemistry, University of Madras, Madras 600 025, India.

The chlorinated dibenzofurans (PCDFs) have received wide publicity and attention in recent years as potential toxic environmental pollutants. Polychlorinated dibenzo-p-dioxins are found as contaminants in commercial polychlorinated biphenyls, chlorinated phenol mixture as well as in certain trichlorophenol derived herbicides. PCDF administered rats showed decrease in body weight. The liver was the major depot of PCDFs, where they were metabolized and excreted mainly through the feces. Since, the liver plays an important role in synthesis, degradation and detoxification pathways, special attention was focussed to study the effect of PCDFs on liver metabolism in rats. In the present investigation a few important enzymes of protein catabolism and blood urea have been studied.
